GOAL: agents that (a) learn policies aligned with human preferences (b) via safe learning/exploration ("Safe RL").

GOAL: agents that (a) learn policies aligned with human preferences (b) via safe learning/exploration ("Safe RL").

Ways to specify optimal policy for RL agent:

- 1. Hand-code reward function before learning.
- 2. Learn rewards or policy from demonstration (IRL or imitation learning)
- 3. Human provides rewards online (TAMER, Active Reward Learning).

GOAL: agents that (a) learn policies aligned with human preferences (b) via safe learning/exploration ("Safe RL").

Ways to specify optimal policy for RL agent:

- 1. Hand-code reward function before learning.
- 2. Learn rewards or policy from demonstration (IRL or imitation learning)
- 3. Human provides rewards online (TAMER, Active Reward Learning).

IRL assumes human demonstrator is optimal up to **random** noise (softmax/Boltzmann)

Humans deviate **systematically** from optimal:

- Biases: hyperbolic discounting, prospect theory.
- Cognitive bounds: forgetting, myopic (limited depth) planning.

0.4

IRL assumes human demonstrator is optimal up to **random** noise (softmax/Boltzmann)

Humans deviate **systematically** from optimal

e.g. Person smokes every week but wishes to quit.

There are decision problems s.t.

- IRL on biased agents can lead to arbitrarily mistaken inferences
- ... but true preferences can be recovered (by modifying IRL)
- Problems are simple, uncontrived: Procrastination, Temptation, Bandits (explore/exploit).

GOAL: agents that (a) learn policies aligned with human preferences (b) via safe learning/exploration ("Safe RL").

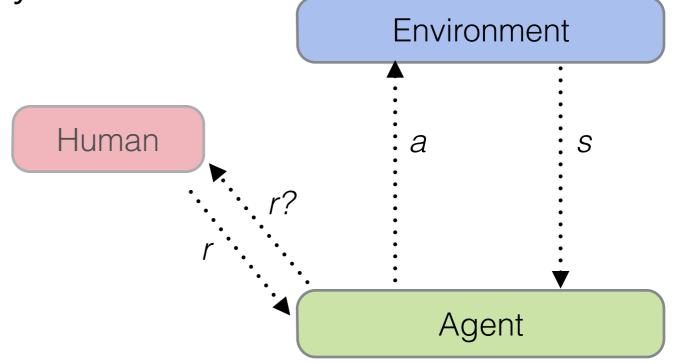

Ways to specify optimal policy for RL agent:

- 1. Hand-code reward function before learning.
- 2. Learn rewards or policy from demonstration (IRL or imitation learning)

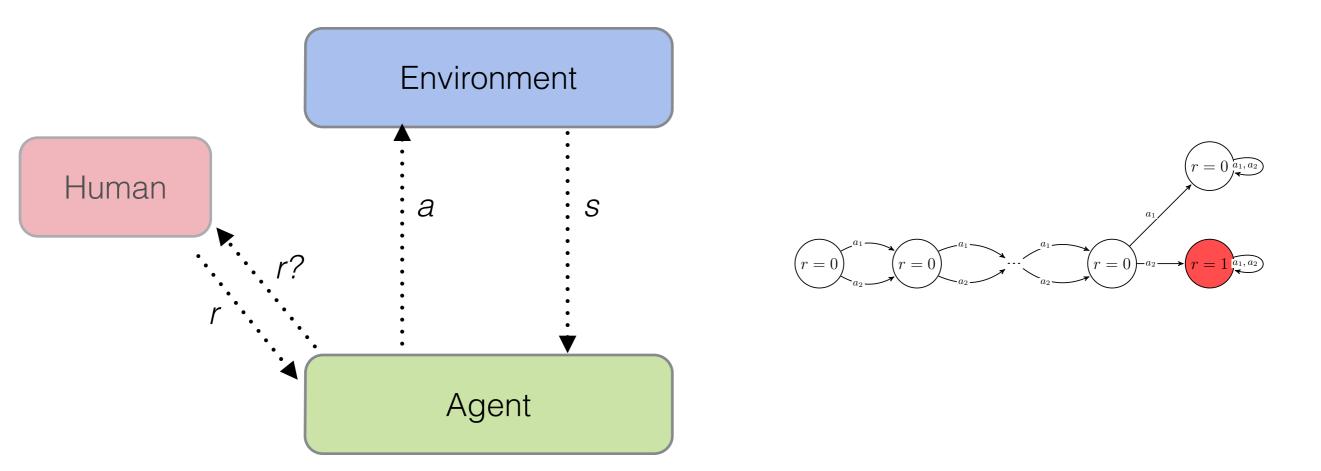

3. Human provides rewards online (TAMER, Active Reward Learning).

Active Reinforcement Learning

- Human provides rewards online
- Label the state-actions that actually occur
- Problem: how to reduce burden on human?
- Active Reinforcement Learning: agent selects which state-actions are labeled by human.

Active Reinforcement Learning

- Agent chooses whether to observe reward R_t on time-step t
- Observing R_t has cost c

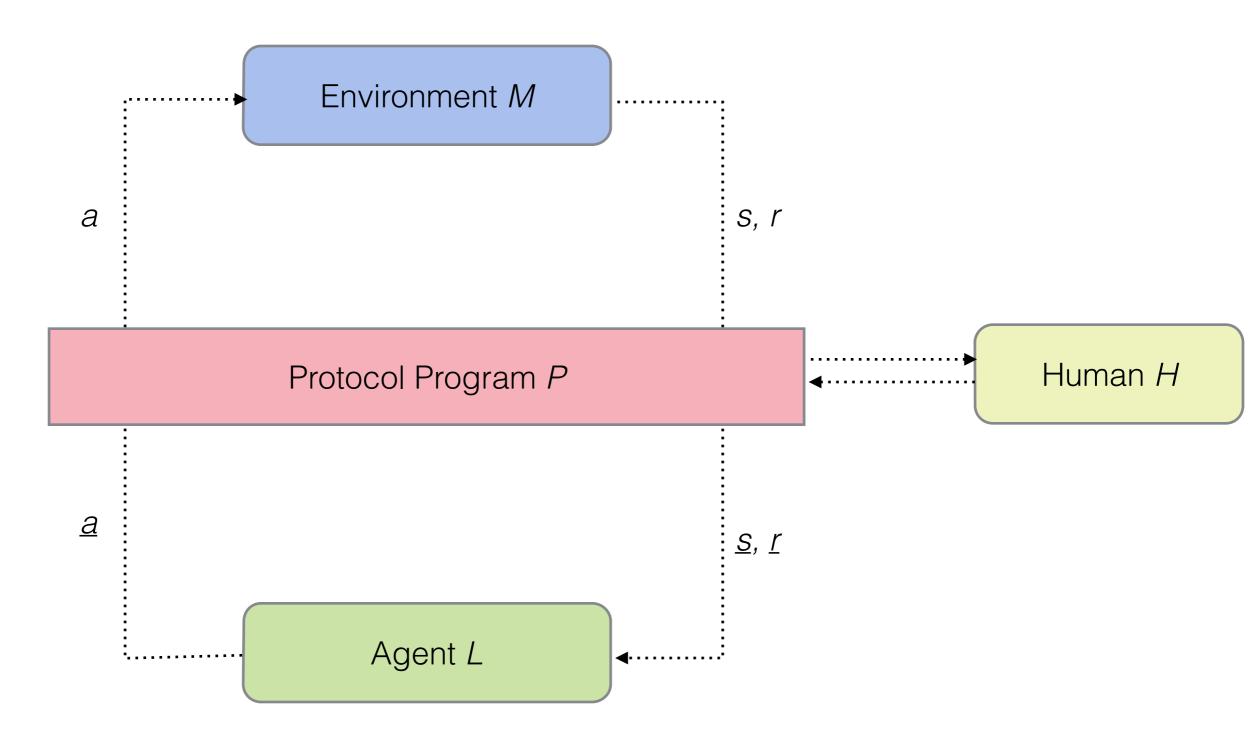

• Goal: maximize
$$\sum_{t} R_t - c q_t$$
, $q_t = \begin{cases} 1 \text{ if } R_t \text{ is observed} \\ 0 \text{ else} \end{cases}$

GOAL: agents that (a) learn policies aligned with human preferences (b) via safe learning/exploration ("Safe RL").

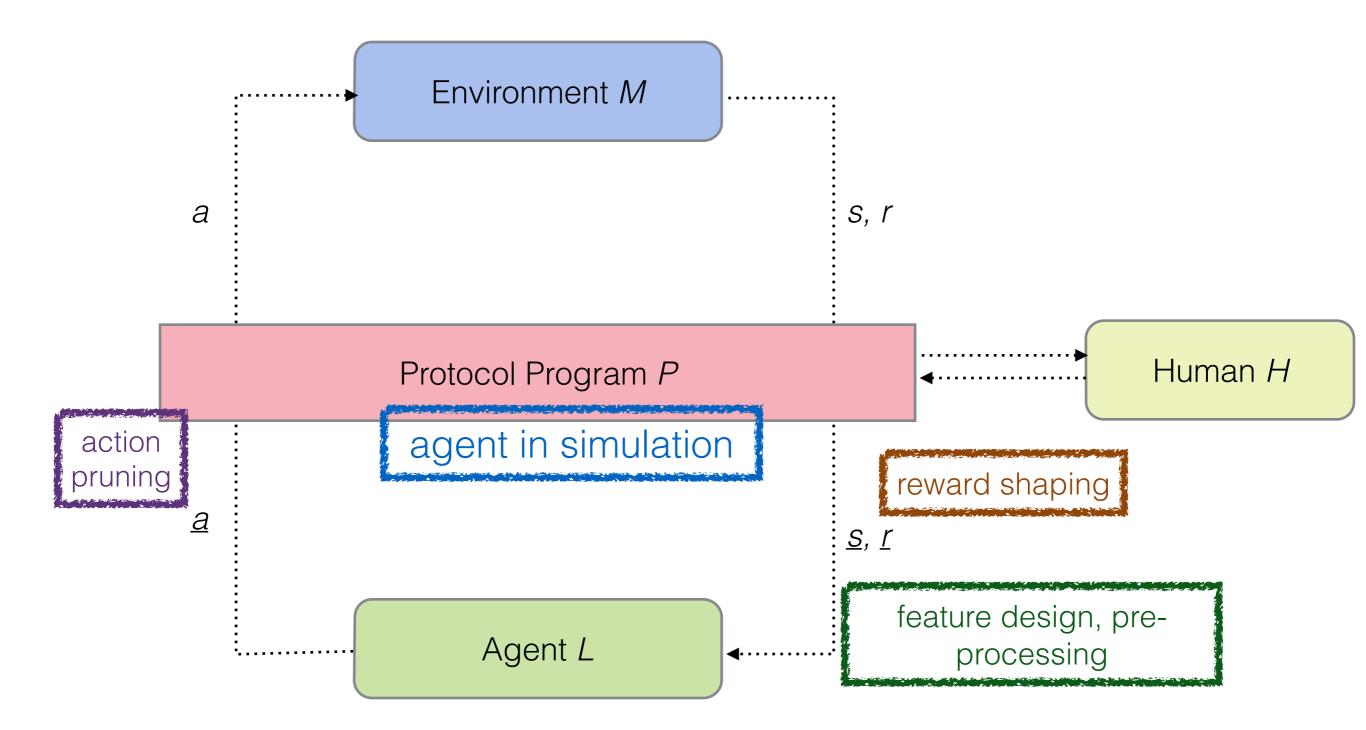

Ways to specify optimal policy for RL agent:

- 1. Hand-code reward function before learning.
- 2. Learn rewards or policy from demonstration (IRL or imitation learning)
- 3. Human provides rewards online (TAMER, Active Reward Learning).

Human-in-the-loop RL

Human teaching for any RL agent

Prevent Catastrophes with Interactive RL

Catastrophic action: action that RL agent should essentially never take, i.e. $P(action) < \epsilon$

Examples:

- breaking laws / moral rules
- ophysically harm humans
- manipulate or psychologically harm humans

Prevent Catastrophes with Interactive RL

Catastrophic action: action that RL agent should never take, i.e. $P(action) < \epsilon$

Examples:

breaking laws / moral rules

ophysically harm humans

manipulate or psychologically harm humans

Prevent Catastrophes with human in loop

Related work: Safe RL and avoiding SREs (Moldovan and Abeel, Frank et al., Paul et. al, Lipton et al.)

Challenge:

- Simulation often inadequate (esp. for extreme events)
- RL agents learn by trial and error (don't know R and T in advance)
- Solution: human blocks catastrophes before they happen

Prevent Catastrophes with human in loop

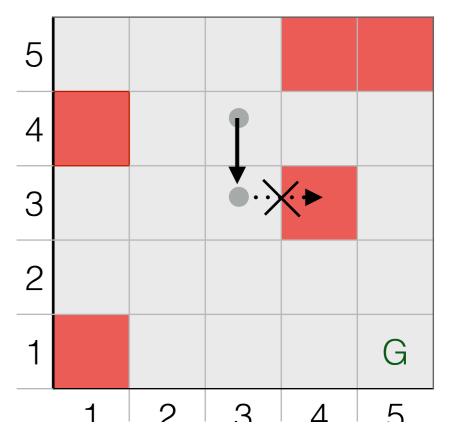

1. Human blocks agent trying bad action,

gives big negative reward.

- 2. Classifier learns to recognize bad actions
- 3. Classifier takes over human role.
- 4. (Human interactively defines a new MDP).

Problems: efficiency, robust generalization.
